

Implicit LES of drag crisis in flow past a circular cylinder

- 計算格子数: 1,001(x) × 501(y) × 301(z) (約1億5千万点)

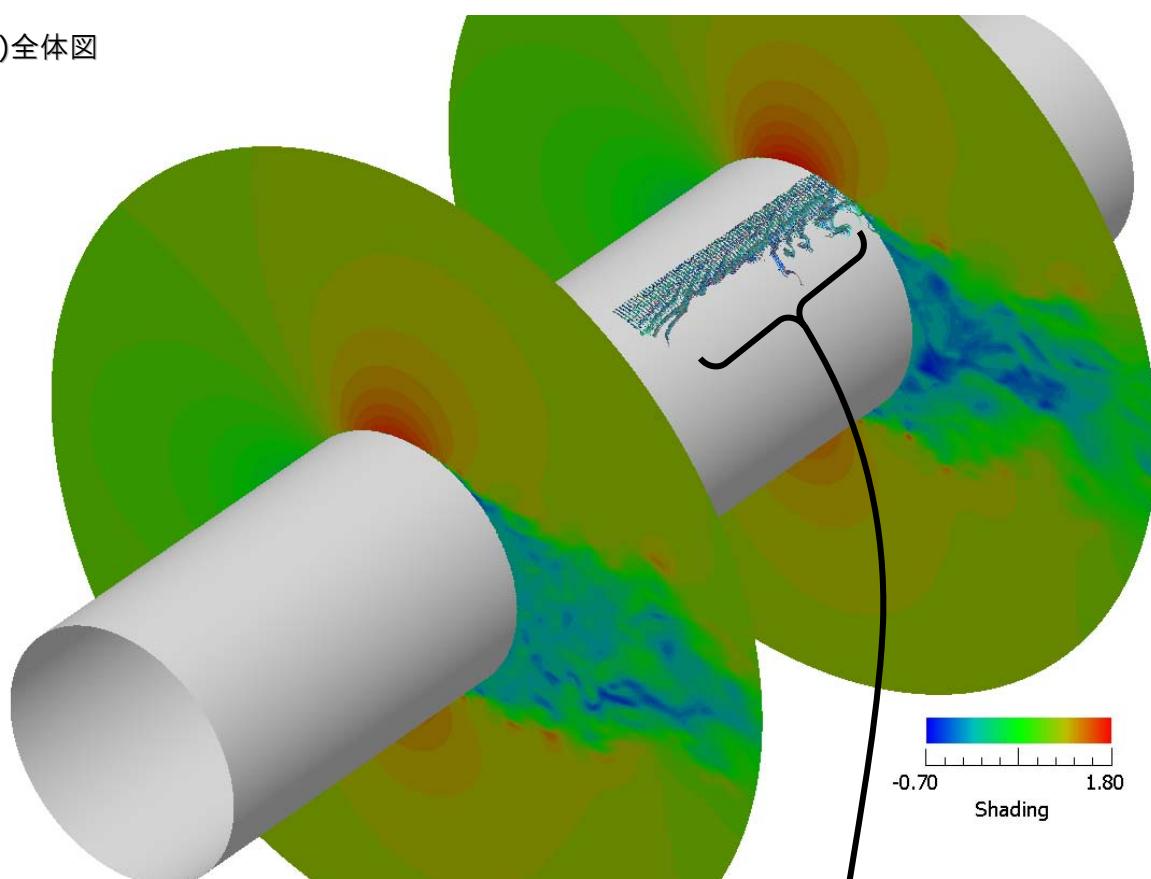

It is well known that the flow past a circular cylinder at critical Reynolds numbers ($Re=3.0\times10^5\text{--}3.5\times10^5$) combines **flow separation**, **turbulence transition**, **reattachment** and **turbulent separation** of a boundary layer on the cylinder. The transition causes the delaying of the separation point and an important reduction of the drag force on the cylinder surface known as the **Drag Crisis**.
